## Motivation

- Minimization of the  $\ell_2$ -regularized average of many functions:

$$\min_{x \in \mathbb{R}^d} \left[ f(x) := \frac{1}{n} \sum_{i=1}^n f_i(x) + \frac{\mu}{2} \|x\|_2^2 \right].$$

- A lot of problems in **machine learning** have this form.

- Big data** setting:  $n$  is very large (millions, billions etc.).

- Incremental/stochastic methods**, whose iteration cost does not depend on  $n$ , are among the most effective methods for this task.

- There exist a lot of incremental methods.
- They all have either a **sublinear** or **linear** convergence rate.
- We propose an incremental method with a **superlinear** convergence rate.

## Assumptions

- All  $f_i$  are twice continuously differentiable and convex.
- The gradients  $\nabla f_i$  and Hessians  $\nabla^2 f_i$  satisfy the Lipschitz condition:

$$\|\nabla f_i(x) - \nabla f_i(y)\|_2 \leq L_f \|x - y\|_2,$$

$$\|\nabla^2 f_i(x) - \nabla^2 f_i(y)\|_2 \leq M \|x - y\|_2$$

for all  $x, y \in \mathbb{R}^d$ .

## The algorithm

**Algorithm** NIM: a Newton-type Incremental Method

**Require:**  $x \in \mathbb{R}^d$ : initial point;  $K \in \mathbb{N}$ : number of iterations.

- Initialize:  $H \leftarrow 0^{d \times d}$ ;  $u \leftarrow 0^d$ ;  $g \leftarrow 0^d$ ;  $v_i \leftarrow$  undefined,  $i = 1, \dots, n$
- for**  $k = 0, 1, 2, \dots, K - 1$  **do**
- Choose an index (cyclic order):  $i \leftarrow k \bmod n + 1$
- Update the average Hessian, scaled center and gradient:
 
$$H \leftarrow H + (1/n)[\nabla^2 f_i(x) - \nabla^2 f_i(v_i)]$$

$$u \leftarrow u + (1/n)[\nabla^2 f_i(x)x - \nabla^2 f_i(v_i)v_i]$$

$$g \leftarrow g + (1/n)[\nabla f_i(x) - \nabla f_i(v_i)]$$
- Move the  $i$ th center:  $v_i \leftarrow x$
- Find the model's minimum:  $\bar{x} \leftarrow (H + \mu I)^{-1}(u - g)$
- Make a step:  $x \leftarrow x + \alpha(\bar{x} - x)$  for some  $\alpha > 0$  (usually  $\alpha = 1$ )
- end for**
- return**  $x$

Assume no subtraction is performed when  $v_i =$  undefined.

## Main idea

- For each  $f_i$  build its own **quadratic model**:

$$m_k^i(x) := f_i(v_k^i) + \nabla f_i(v_k^i)^\top (x - v_k^i) + \frac{1}{2}(x - v_k^i)^\top \nabla^2 f_i(v_k^i)(x - v_k^i).$$

- Together they form a quadratic model of  $f$ :

$$m_k(x) := \frac{1}{n} \sum_{i=1}^n m_k^i(x) + \frac{\mu}{2} \|x\|_2^2.$$

- Step:  $x_{k+1} := x_k + \alpha_k(\bar{x}_k - x_k)$ , where  $\bar{x}_k := \operatorname{argmin}_x m_k(x)$ .

- Update **only one** component  $m_k^i$  at each iteration.

## Theorem (local convergence)

- Let all the centers be initialized close enough to the optimum  $x^*$ :

$$\|v_0^i - x^*\|_2 \leq \frac{2\mu}{M\sqrt{n}}, \quad i = 1, \dots, n.$$

- Assume the unit step length  $\alpha_k \equiv 1$  is used.

- Then  $\{x_k\}$  converges to  $x^*$  at an **R-superlinear** rate:

$$\|x_k - x^*\|_2 \leq r_k \quad \text{and} \quad \lim_{k \rightarrow \infty} \frac{r_{k+1}}{r_k} = 0.$$

- More precisely, the convergence rate of  $\{x_k\}$  is  **$n$ -step R-quadratic**:

$$r_{k+n} \leq \frac{M}{2\mu} r_k^2, \quad k = 2n, 2n + 1, \dots$$

## Theorem (global convergence)

- Denote the condition number of  $f$  as  $\kappa := (L_f + \mu)/\mu$ .

- Assume a constant step:  $\alpha_k \equiv \alpha < \bar{\alpha} := 2\kappa^{-3}(1 + 19\kappa(n-1))^{-1}$ .

- Then, for any initialization,  $\{x_k\}$  converges to  $x^*$  at an **R-linear** rate:

$$\|x_k - x^*\|_2 \leq \sqrt{\kappa} \cdot c^{k/2} \|x_0 - x^*\|_2,$$

where  $c := h^{1/(1+2(n-1))}$  for  $h := 1 - 2\kappa^{-1}\alpha + \kappa^2(1 + 19\kappa(n-1))\alpha^2$ .

## Theoretical comparison

Method	Iteration cost	Memory	Convergence rate	
			In iterations	In epochs
SGD [1]	$O(D)$	$O(D)$	Sublinear	Sublinear
SAG [2]	$O(D)$	$O(ND)$	Linear	Linear
SFO [3]	$O(ND)$	$O(ND)$	Linear?	Linear?
<b>NIM</b>	$O(D^3)$	$O(ND + D^2)$	<b>Superlinear</b>	<b>Quadratic</b>

## Linear models

- Linear models:**  $f_i(x) := \phi_i(a_i^\top x)$  for some  $a_i \in \mathbb{R}^d$ .

- The gradients and Hessians have a **special structure**:

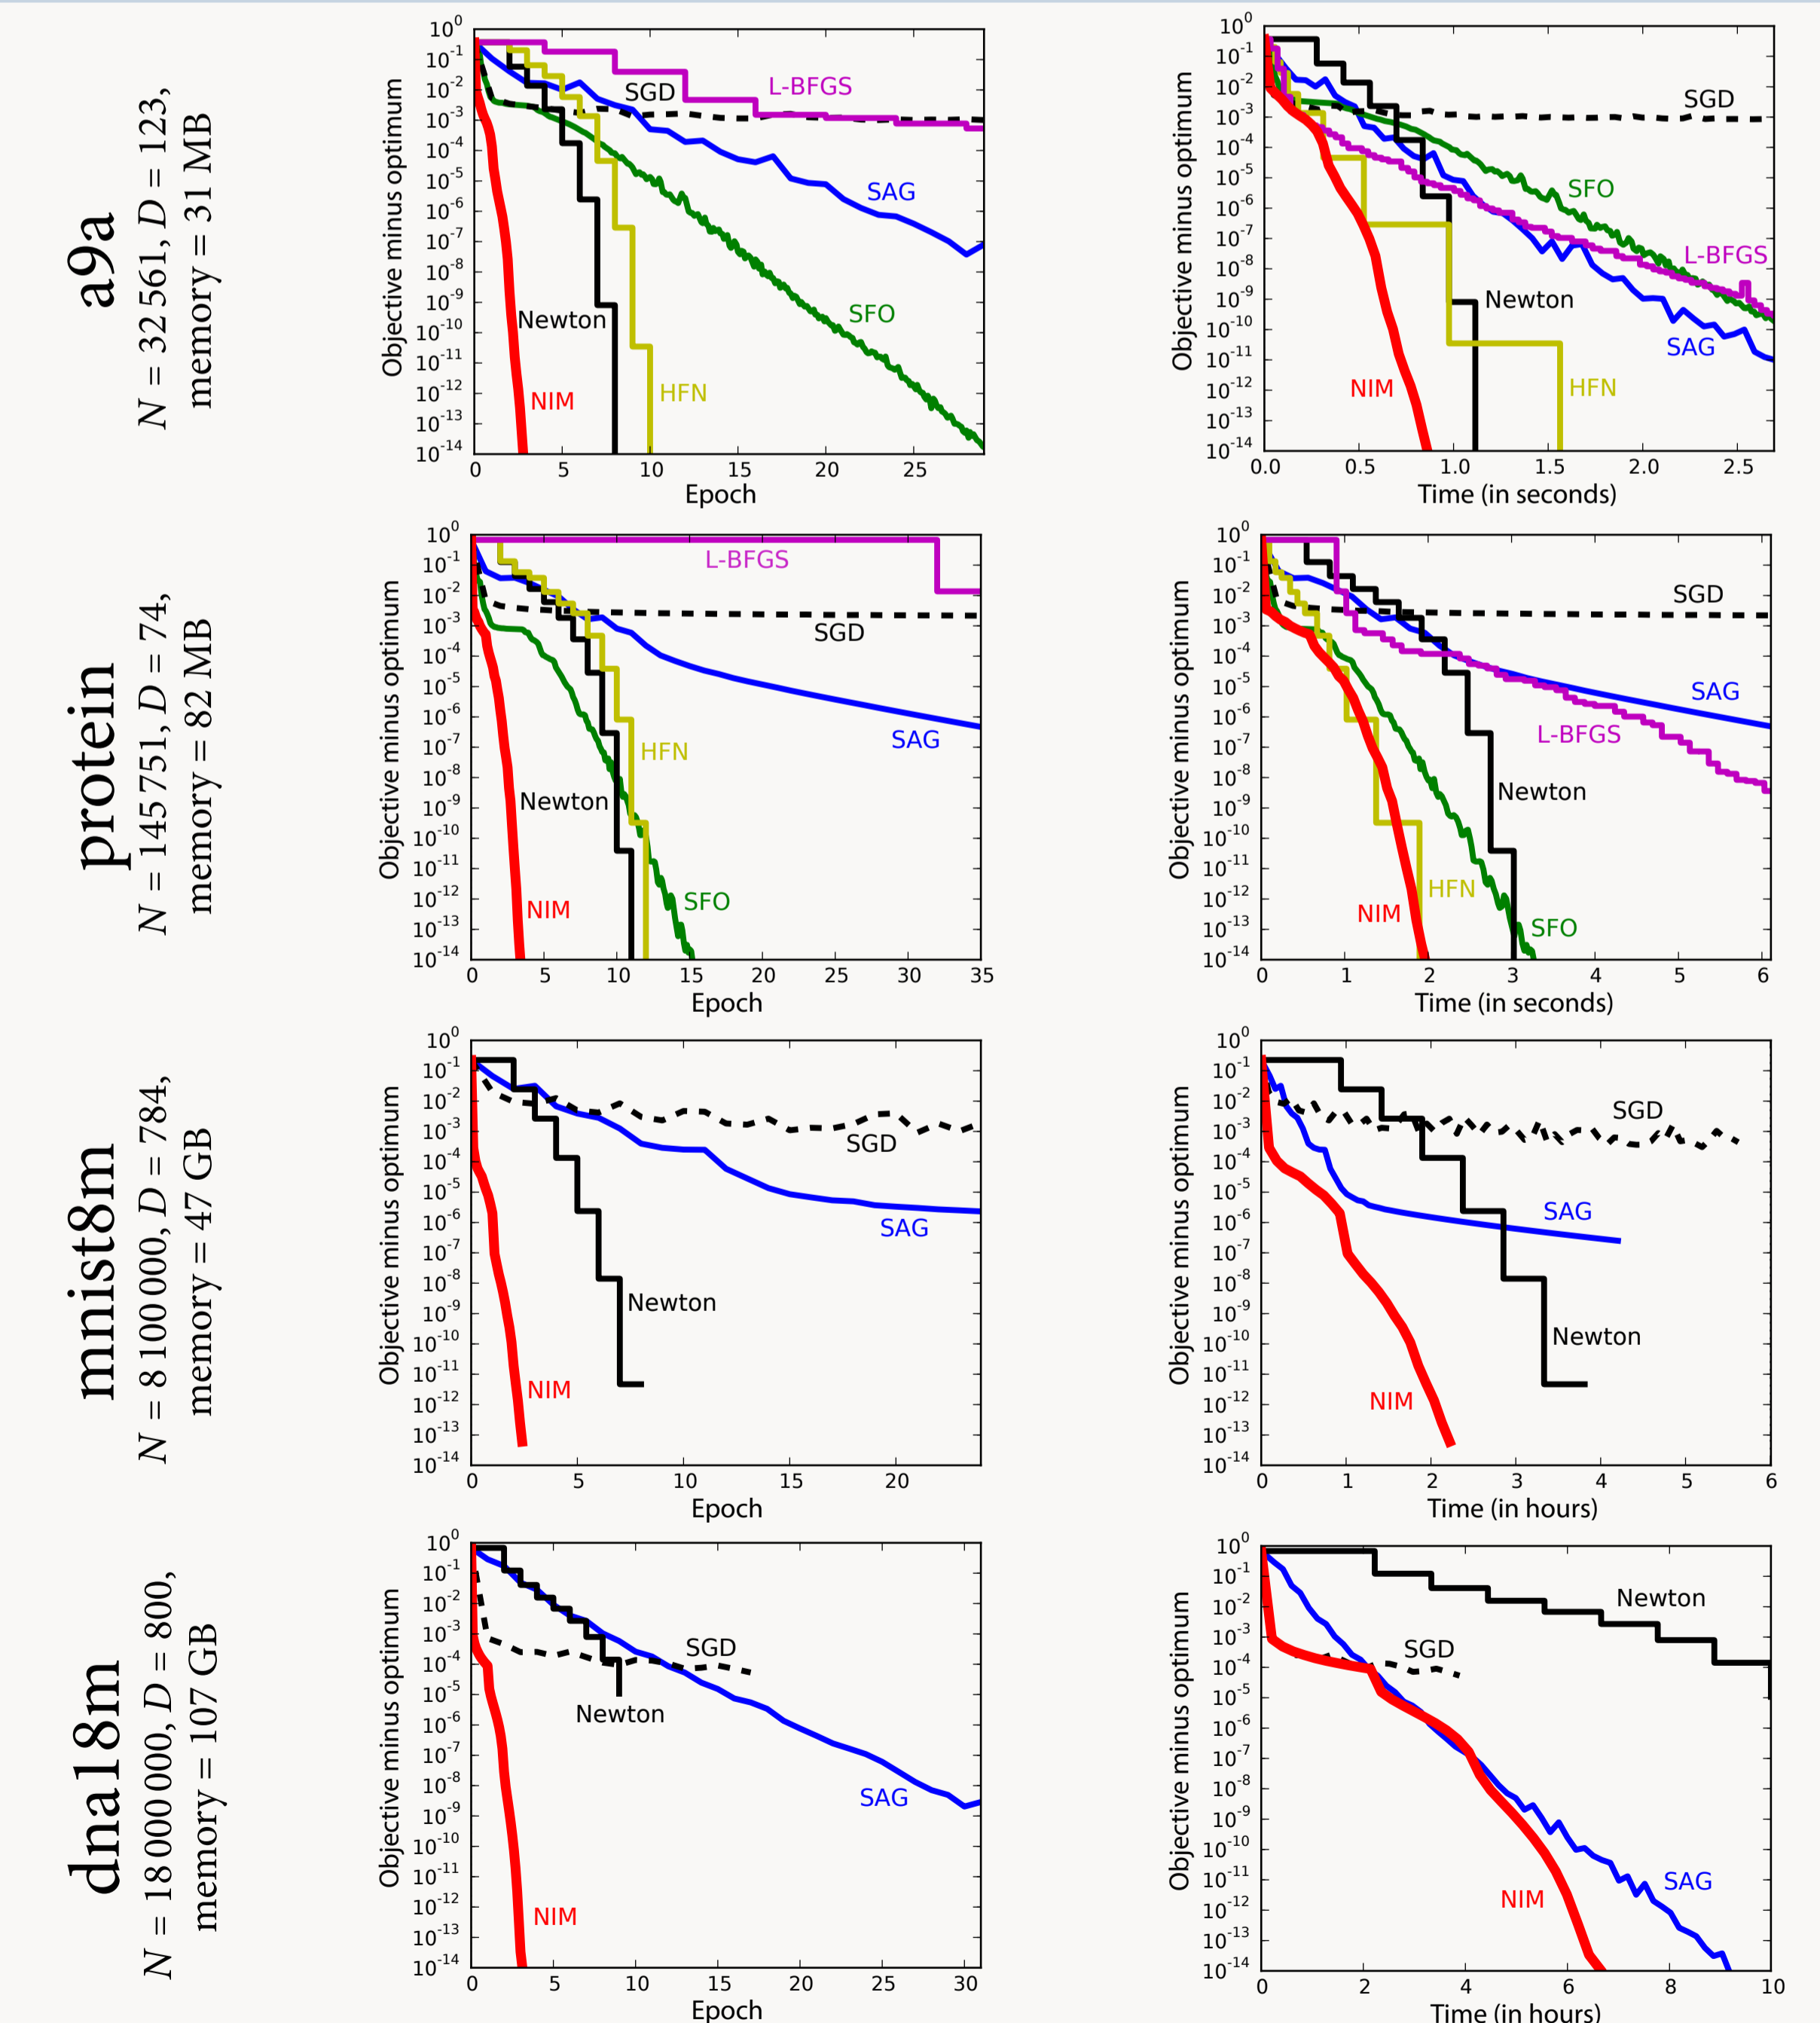

$$\nabla f_i(x) = \phi_i'(a_i^\top x) a_i \quad \text{and} \quad \nabla^2 f_i(x) = \phi_i''(a_i^\top x) a_i a_i^\top.$$

- Instead of  $v_k^i$  store the corresponding **dot products**  $v_k^i := a_i^\top v_k^i$ .

- Work directly with  $B_k := (H_k + \mu I)^{-1}$  using **rank-1 updates**.

Method	Iteration cost	Memory	Convergence rate	
			In iterations	In epochs
SGD	$O(D)$	$O(D)$	Sublinear	Sublinear
SAG	$O(D)$	$O(N + D)$	Linear	Linear
<b>NIM</b>	$O(D^2)$	$O(N + D^2)$	<b>Superlinear</b>	<b>Quadratic</b>
